### AIM: Create your first Hello World iOS app in SwiftUI

**1.** Create a new iOS app by selecting  $File \rightarrow New \rightarrow Project...$  from the Xcode menu. Choose the *App* template from the *Application* section in the iOS tab.

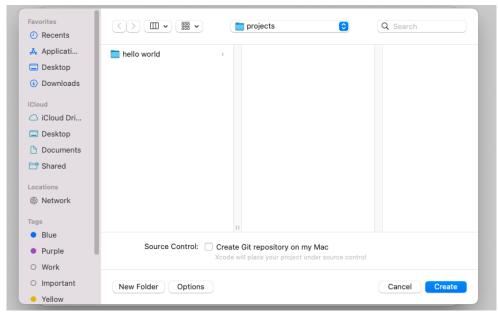

- (a) Name the app *hello world*.
- (b) Xcode uses name to set the bundle identifier for the app.
- (c) Select *SwiftUI* for the technology used to build the app's user interface.
- (d) Set *Swift* for the programming language used to code the app.
- (e) Ensure that the Core Data and unit testing options are not selected. You don't need local databases to store the app's data since it's elementary. There is also no need to test the code of such a basic app.

(f) Finally, check the *Create Git repository on my Mac* for your project and save it. It's useful to initialize a <u>Git</u> repository for any project you create since you will likely need it

#### 2. Understanding the structure of a basic SwiftUI iOS app

- (a) The hello world project has two source code files. You can choose either one of them from the project navigator on the left side of the Xcode editor.
- (b) Open the *hello\_worldApp.swift* file and take a look at the code.

```
import SwiftUI
@ main
structhello_worldApp: App {
    var body: some Scene {
        WindowGroup {
            ContentView()
        }
    }
}
```

(c) The most important thing you should be aware of is that you are using a *structure*, which is a custom Swift data type, to define the main scene of the app. The scene handles a group of views of the app. There is only one view, in this case, declared in

hello world 1 import SwiftUI Manual Market
Market struct ContentView: V ✓ ■ hello world var body: some Vi hello\_worldApp Text("Hello, " .padding() Assets } 8 } > Preview Content 10 struct ContentView\_Pr static var previe 12 ContentView() 14 }

Open the *ContentView.swift* file. And take a look the code:

```
structContentView: View {
          var body: some View {
                Text("Hello, world!")
                .padding()
          }
}
```

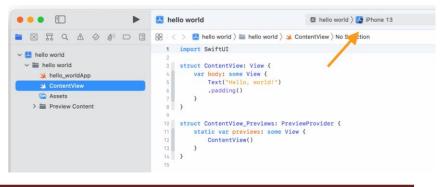

#### (3) Run your first iOS app in the simulator.

You don't need an iPhone to run basic apps. A simulator has all of the essential features of an actual

device, and it is much easier to run

an app using this.

(a) The first step is to choose the iOS simulator that you want to run the app on. A default simulator is already selected at the top of your Xcode project

Name: Rathod Dharmendrasinh Vipulsinh

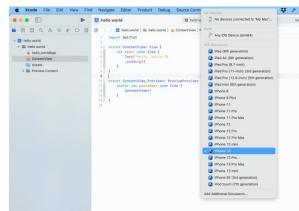

window.

(b) You can click on the default simulator and choose a custom one from the simulator menu

| Mello world |

(c) Press the play button at the top left of the

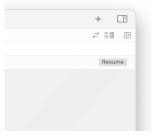

project window to run the app.

The project <u>builds</u> itself without errors and then runs the app on the chosen simulator

• SwiftUI also allows you to preview the app's appearance without running the app on a simulator. To do this, switch to the *ContentView.swift* file and look at the preview code.

• The code creates a structure that handles the updates of the app's main view to preview them. You can press the resume button at the top right of the

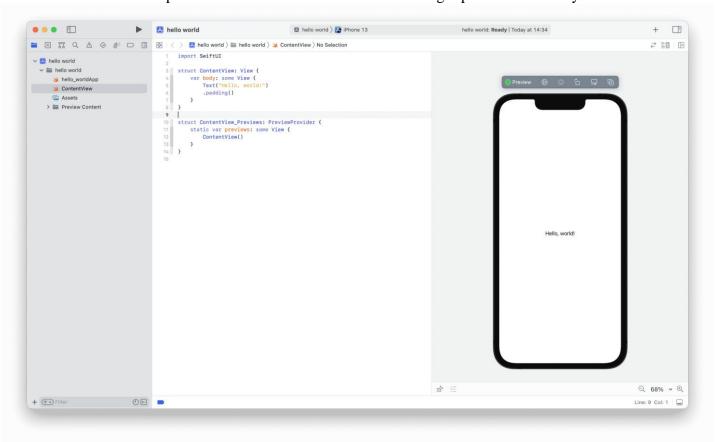

preview window to preview the changes

The preview simulator is perfectly synchronized with the code of the view. This means that any changes you make

to the code in the left panel can be seen in the simulator in the right panel immediately.
